Abstract—Software architecture is considered as a set of architectural design decisions. Capturing and representing architectural design decisions during the architecting process is necessary for reducing architectural knowledge evaporation. Moreover, managing the evolution of architectural design decisions helps to maintain consistency between requirements and the deployed system. In this paper, we create the Triple View Model (TVM) as a general architecture framework for documenting architectural design decisions. The TVM clarifies the notion of architectural design decisions in three different views and covers key features of the architecting process. Based on the TVM, we propose a scenario-based methodology (SceMethod) to manage the documentation and evolution of architectural design decisions. We also conduct a case study on an industrial project to validate the applicability and the effectiveness of the TVM and the SceMethod. The results show they provide complete documentation on architectural design decisions for creating a system architecture, and well support architecture evolution with changing requirements.

Keywords—architectural design decision; architecture documentation; architecture evolution; scenario; architectural knowledge

I. INTRODUCTION

Software architecture plays an important role in achieving functional and non-functional requirements. The architecting process provides a high-level framework to support designing, developing, testing, and maintaining software systems after deployment. The traditional concept of software architecture focuses on components and connectors, as Perry/Wolf proposed in [1]. Although the achievement by recognizing components and connectors is significant in research and industry, some problems still remain in software architecture theory and practice. As the most critical aspects of the problems for researchers and practitioners, architectural knowledge representation and knowledge evaporation have major influence on complexity and cost of system evolution, communication among stakeholders, and software architecture reuse.

Perry and Wolf considered the selection of elements and their form to be architectural design decisions, and the justification for these decisions to be found in the rationale. It was not until 2004, with Bosch’s paper [2] at the European Workshop on Software Architecture, that software architecture has finally come to be considered as a set of architectural design decisions. This specific focus on architectural design decisions led to a broader focus on architectural knowledge [3]. Capturing and representing architectural design decisions helps to organize architectural knowledge and reduce its evaporation, thus providing a better control on many fundamental architectural drift and erosion problems in the software life cycle. In the research related to our work, the focus has been on the development of models and tools to capture, manage, and share architectural design decisions [4–6]. A brief comparison and analysis of the existing models and tools has been conducted in [7]. However, there is still no agreed notion on what should be considered as an architectural design decision during an architecting process. Besides, current models and tools do not support architecture evolution very well, which is also critical for architectural knowledge management and needs more attention in research and industry [8].

To address this need, we propose the Triple View Model (TVM) as a general architecture framework of architectural design decisions. The TVM divides architectural design decisions set into three different views, i.e., the element view, the constraint view, and the intent view. These three views specify architectural design decisions by three aspects, “what”, “how”, and “why”, and all the architectural design decisions are regarded as a software architecture. In addition, based on the TVM, we present a scenario-based methodology (SceMethod) for architectural design decisions documentation and evolution, which enables us to manage architectural knowledge effectively. We subsequently conduct a case study to validate our TVM and SceMethod.

We make the following three contributions:

1) The TVM - A general framework of architectural design decisions. The “what” - “how” - “why” triple view clarifies the notion when documenting architectural design decisions;

2) The SceMethod - A scenario-based approach to architectural design decisions documentation and evolution. It provides an effective way to derive architectural design decisions and keep architectural knowledge complete and consistent during architecture evolution;

3) The substantial case study - A validation for the TVM and the SceMethod on an industrial project. The results demonstrate the applicability and the effectiveness of the TVM and the SceMethod.
The rest of this paper is organized as follows. Section 2 discusses the Triple View Model in detail, and section 3 describes the scenario-based method of architectural design decisions documentation and evolution. In section 4, we conduct a case study to validate the TVM and the SceMethod in an industrial project. Section 5 introduces related work on architectural design decision models and architecture evolution, and we conclude the paper in section 6.

II. TRIPLE VIEW MODEL

The Triple View Model provides a fundamental framework of architectural design decisions and covers key features of the architecting process. It has the following advantages:

- First, the TVM captures architectural design decisions not only on components, connectors, and their relationships, but also on intent behind each design decision. It is essentially consistent with the traditional concept of software architecture, and helps researchers and practitioners grasp both the fundamental concepts and the decision making strategies in an architecting process;
- Second, the TVM enables us to establish a complete set of architectural knowledge, which provides clear directions for communication among different stakeholders in the software development life cycle;
- Third, the TVM supports scenario-based architectural design decisions documentation and evolution, and finally supports software architecture evolution.

A. Framework

The TVM is defined by three views: the element view, the constraint view, and the intent view. This is analogous to Perry/Wolf model’s elements, form, and rationale but with expanded content and specific representations. Each view in the TVM is a subset of architectural design decisions, and the three views constitute an entire architectural design decisions set. Specifically, the three views mean three different aspects when creating an architecture, i.e., “what”, “how”, and “why”, as shown in Fig. 1. The three aspects aim to cover design decisions on “what” elements should be selected in an architecture, “how” these elements combine and influence each other, and “why” a certain decision is made.

During the architecting process in the software life cycle, architects are the main role operating architectural design decisions. However, architectural decisions may also be brought forward by programmers, project managers, or customers in real software project environment. In any case, the TVM provides a right selection of architectural design decisions, and it is applicable for all stakeholders. Moreover, the TVM suggests a systematical way to include complete architectural decisions for creating an architecture. Fig. 2 shows the relations among architectural design decisions, the TVM and software architecture in a system.

B. Model

Here, we discuss the detailed contents of each view in the Triple View Model, which are illustrated in Fig. 3.

In the element view, the architectural design decisions describe “what” elements should be selected in an architecting process. We define computation elements, data elements, and connector elements in this view. Computation elements represent processes, services, and interfaces in a software system. Data elements indicate data accessed by computation elements. Both computation elements and data elements are regarded as components in software architecture, and connector elements are communication channels between those components in the architecture. Note that the architectural design decisions in the element view consist of traditional architecture concepts, which are mainly represented by components and connectors.

In the constraint view, the architectural design decisions are defined as behavior, properties, and relationships. They describe constraints on system operations and are typically derived from requirement specifications. Specifically, behavior illustrates what a system should do and what it should not do in general. It specifies prescriptions and proscriptions based on requirement specifications, and influences the design decisions in the element view. Properties are defined as constraints on a single element in the element view, and relationships mean interactions and configurations among
The architectural design decisions in the intent view are composed of rationale and best-practices in the architecting process. Rationale, which includes alternatives, motivations, trade-offs, justifications and reasons, is generated when analyzing and justifying every decision that is made. Best-practices are styles and patterns we choose for system architecture and design. The architectural decisions in the intent view mainly exist as tacit knowledge [9], and we need to document them during the decision making process, so that stakeholders can clearly understand these tacit architectural knowledge during the architecting process. What’s more, the consistent communication among different stakeholders effectively decreases architectural knowledge evaporation.

III. SCENARIO-BASED DOCUMENTATION AND EVOLUTION METHOD

In this section, we propose the scenario-based architectural design decisions documentation and evolution method (SceMethod).

The TVM is the foundation of architectural design decisions documentation and evolution. In the SceMethod, we aim to obtain and specify the element view, constraint view, and intent view through end-user scenarios, which are represented by Message Sequence Charts (MSCs). Most functional requirements can be represented by end-user scenarios through MSCs; while non-functional requirements and quality attributes probably cannot be directly shown in the scenarios. However, in the end, all non-functional properties can be reified functionally into architecture design decisions, so that we still can manage non-functional properties in the SceMethod. Fig. 4 illustrates the SceMethod process. We can see that for the first time we apply this method, we obtain initial architectural design decisions results. Later on, as the requirements change, the architectural decisions are evolved and refined according to the newly requirements. By documenting all the possible architectural design decisions and evolving these decisions with changing requirements, the SceMethod effectively makes architectural knowledge explicit and reduces architectural knowledge evaporation.

A. Initialization

Before applying the TVM to end-user scenarios, the requirements of the software system are elicited, and then we use MSCs to describe both the positive and negative scenarios. MSC is used for representing end-user scenarios through MSCs; while non-functional requirements and quality attributes probably cannot be directly shown in the scenarios. However, in the end, all non-functional properties can be reified functionally into architecture design decisions, so that we still can manage non-functional properties in the SceMethod. Fig. 4 illustrates the SceMethod process. We can see that for the first time we apply this method, we obtain initial architectural design decisions results. Later on, as the requirements change, the architectural decisions are evolved and refined according to the newly requirements. By documenting all the possible architectural design decisions and evolving these decisions with changing requirements, the SceMethod effectively makes architectural knowledge explicit and reduces architectural knowledge evaporation.
messages among the four agent instances. Based on the end-user scenarios represented by MSCs, we initially derive the architectural design decisions as defined in the TVM. If the scenarios change afterward, we then track the evolution of the decisions and refine them based on the changing requirement specifications. The following three steps illustrate the complete ScenMethod process.

B. From MSC Syntax to Element View

As we mentioned previously, the element view captures architectural design decisions on components and connectors we need in the architecting process. Since an MSC is associated with several agent instances, we can derive the element view directly from the syntax of MSCs.

Specifically, each agent instance is taken as a computation element, which includes its services or interfaces according to requirement specifications. Besides, from the interaction messages between the source and target agent instances, we can extract data elements that accessed by computation elements. Connector elements serve as communication channels between computation elements.

Therefore, the element view is derived as follows:

$$\text{Computation Elements} = \{\text{Agent Instances}\}$$

$$\text{Data Elements} = \{\text{Interaction Messages}\}$$

$$\text{Connector Elements} = \{\text{Channels between Agents}\}$$

From the syntax of MSCs, the element view is initially documented. When new scenarios are introduced by end-users, the element view is then evolved and refined based on updated MSCs.

C. From MSC Semantics to Constraint View

Based on the semantics of MSCs, we analyze behavior, properties, and relationships of the goal system, in order to document architectural design decisions in the constraint view.

In terms of behavior, we focus on general functionality of the system that is specified by the end-user scenarios, i.e., the prescriptions and the proscriptions. Typically, in the end-user scenarios, positive scenarios describe the desirable behavior of the system, while negative scenarios describe the undesirable behavior. Therefore, we can tell what the system should do from positive scenarios, and what should not do from negative scenarios as well as exceptions handled in the MSCs. Through this information, the architectural design decisions on the behavior of the system are documented by the following steps:

$$\text{Behavior} = \{\text{Prescriptions, Proscriptions}\}$$

$$\text{Prescriptions} = \{\text{Positive Scenarios}\}$$

$$\text{Proscriptions} = \{\text{Negative Scenarios, Exceptions}\}$$

Properties in the constraint view mean the constraints on a single element. We use “Receive”, “Issue”, and “Check” factors to define properties.

$$\text{Properties} = \{\text{Receive, Issue, Check}\}$$

“Receive” and “Issue” factors identify the responsibility of each element. For a computation element, “Receive” factor indicates the data which inputs to the element, and “Issue” factor means the data which outputs from the element. Both of them are achieved according to the message interactions in the MSCs. If the element is a data element or a connector element, the “Receive” and “Issue” factors are specified as the corresponding computation elements directly operating the data element or connected by the connector element. “Check” factor is the precondition and the postcondition for an element according to requirement specifications. Generally, properties capture architectural decisions for a single element, through which we are able to grasp the responsibility of the element and the requirement constraints on the element.

Relationships are architectural design decisions on interactions and configurations among different elements. In order to find out the interactions among agent instances, we use simple path expressions to illustrate the interacted events in the MSCs.

$$\text{Relationships} = \{\text{Event Traces by Path Expressions}\}$$

The event traces provide us with general information about the interaction among agent instances. Based on the event traces results, the couplings and the structure of the components are obtained. Additionally, interactions and configurations among different elements provide a blueprint for us to choose architectural styles and patterns for subsequent architecting and designing process.

D. Intent View Documentation

Documenting the intent, i.e., decision making strategy, is necessary for communicating clearly among different stakeholders and keeping architectural knowledge complete in the software development life cycle. Since decision making strategies are usually behind architects and other stakeholders’ thoughts, the intent view cannot be derived and evolved directly from MSCs as the element and constraint view, which make it difficult to define a formal specification for documenting the intent view. The best way to make the intent explicit is to record decision making strategies
as the architecting process moves forward. Specifically, answering each question that occurs to the stakeholders in the architecting and designing phase is helpful to constitute the architectural design decisions in the intent view. For instance, we may document the motivations why we choose some elements as computation elements while others as connector elements, and the reasons that we put a certain property on an element, etc. Basically, rationale evolves together with the element view and the constraint view. When the decisions in the element and constraint view change, the documented rationale is to be updated as well in order to keep the architectural knowledge up-to-date.

Besides, architectural styles, architectural patterns and design patterns that we apply as best-practices should also be recorded as design decisions in the intent view. At the same time, the justifications, alternatives, and trade-offs generated when selecting a certain best-practice during the decision making process are documented in the rationale as well.

In conclusion, the intent view are documented in two aspects:

$$Rationale = \{Answers \ or \ Solutions \ to \ The \ Intent-Related \ Questions\}$$

$$Best-Practices = \{Architectural \ Styles, \ Architectural \ Patterns, \ Design \ Patterns\}$$

The intent view is as important as the element and constraint view, and is critical for architectural knowledge management. Therefore, when we update the element view and the constraint view according to the changing requirements, it is necessary to update the intent view as well.

IV. CASE STUDY: VALIDATION IN A POWER PLANT MONITORING SYSTEM

Our TVM and SceMethod have been validated in a substantial case study on an industrial project provided by the Italian electrical company ENEL [11]. In this project, an information system is designed to manage ENEL’s thermal power plant operations. The purpose of the project aims to improve power plant efficiency, to reduce operation and maintenance costs, and to avoid forced outages [12]. Therefore, a power plant monitoring system is to be established with functions such as data acquisition from the field through sensors, fault detection in the power plant, and alarm raising in case of fault occurred. The main requirements of the system is gathered from [13–15].

Perry and Brandozzi have presented a method that transforms the goal oriented requirement specifications into architectural prescriptions [16, 17]. The power plant monitoring system has already been applied in a case study by using Perry/Brandozzi’s method [18]. We conducted the case study on the same real world project. On the one hand, we assessed the applicability of the TVM and the SceMethod for a real industrial project; on the other hand, we further evaluated the effectiveness of the TVM and the SceMethod by comparing our results with those in the previous case study which used Perry/Brandozzi’s method.

A. Research Questions

The TVM and the SceMethod provide a general architecture framework and a complete process to support the documentation and evolution of architectural design decisions. This leads to the following research questions:

RQ1: Are the TVM and the SceMethod feasible when applied to real scenarios in an industrial project context?

RQ2: How well do the architectural design decisions derived from the SceMethod cover the main architectural specifications and issues?

RQ3: How well do the derived results on architectural design decisions support architecture evolution?

We conducted a case study to address these questions. We describe our end-user scenarios, results, analysis, and discussion respectively.

B. End-user Scenarios

Based on the requirement specifications of the power plant monitoring system, we established end-user scenarios to cover the functionality of the system, including all the positive scenarios and some of the negative scenarios. Fig. 6 and Fig. 7 show the MSC specifications for the positive and negative scenarios of the power plant monitoring system.

C. Results

Taking the MSC specifications as the input, we followed the SceMethod to derive the architectural design decisions of the power plant monitoring system.

1) Element View: From the syntax of the MSCs in Fig. 6 and Fig. 7, all the agent instances are considered as the computation elements, and the information transmitted by the interaction messages are the data elements. We defined four connector elements as the channels between the source and target computation elements. Table I shows the element view of the power plant monitoring system.

2) Constraint View: From the semantics of the MSCs, we derived architectural design decisions on behavior, properties, and relationships of the power plant monitoring system. First of all, we focused on the behavior of the system. The positive and the negative scenarios tell the system behavior, and each conclusion we draw from the end-user scenarios can be seen as an architectural design decision on system behavior. Such as “when the Alarm Manager receives fault information, it should send alarm information to the UpdateDB Manager to update the database” and “If the FaultDetection Engine does not receive abnormal sensor information, it should not release fault information”. The architectural design decisions relevant to the system
Figure 6. MSC Specifications of the Power Plant Monitoring System (positive scenarios)

Figure 7. MSC Specifications of the Power Plant Monitoring System (negative scenarios)
behavior provide us general functionality of the power plant monitoring system, based on which we find out the detailed system architecture through further analysis.

Secondly, we documented the properties of each element in the element view. The results are shown in Table II. From these results, the responsibility of each element enables us to extract the requirement constraints (precondition and postcondition) that we need to comply with in the later architecting and designing process.

As for relationships among different elements, we obtained each event trace from the end-user scenarios. Based on all the event traces from the end-user scenarios, we captured the coupling relationship among the computation elements, data elements, and connector elements. Structure diagram is the best way to show how each element related to others to establish the complete architecture. We illustrated the structure diagram of the power plant monitoring system in Fig. 8, which is generated from the event traces.

3) Intent View: Since the intent view reflects the thoughts behind stakeholders’ head during the architecting process, as mentioned previously, we documented the answers to the questions that concerned with the decision making process as architectural design decisions.

For the sake of brevity, we did not specify all the possible decisions in the intent view. We only illustrated some questions as examples here, which are shown in Table III. Answers to these questions provide us with the intent during the architecting process.

### D. Analysis

RQ1: Are the TVM and the SceMethod feasible when applied to real scenarios in an industrial project context?

The power plant monitoring system is an industrial project that supported by the Italian company ENEL. We note that after we have described the end-user scenarios based on the requirement specifications of the system, it is easy to apply the TVM and the SceMethod to those scenarios to derive most of the architectural design decisions. Basically, the end-user scenarios specified by MSCs enable us to obtain the element view, the constraint view, and the intent view respectively according to the SceMethod.

RQ2: How well do the architectural design decisions derived from the SceMethod cover the main architectural specifications and issues?

Table I shows all the components and connectors that we need to establish the power plant monitoring system. Comparing with the previous case study by using Perry/Brandozzi’s method on the same system, we find that the elements generated from the SceMethod have covered all
the process components, data components, and connectors from Perry/Brandozzi’s method [18]. However, there is a little difference that we have one more computation element, i.e., the Sensor Manager, in our element view. Because by providing more computation elements, we can make the architecture more flexible, which helps to support detailed functionality and is also easier for us to manage the coupling and the evolution of the architecture. Table II indicates that the properties enable us to clarify the responsibility of each element and the requirement constraints that need to be considered in the future designing process. In addition, in order to establish a whole blueprint of the goal system, we generate Fig. 8 based on the relationships among all the computation and connector elements, which is similar as the box diagram in the architecture results using Perry/Brandozzi’s method [18]. Note that the architectural decisions derived from the SceMethod have covered all the architecture prescriptions from Perry/Brandozzi’s method, and in our case study, the main issues on the components, connectors, and their relationships have been achieved as well when deriving architectural design decisions. Furthermore, we captured all the possible intent-related design decisions, which are then used to record and track the architectural knowledge and the decision making process during the architecting phase. On the contrary, the intent-related decisions were not mentioned in Perry/Brandozzi’s method.

**RQ3:** How well do the derived results on architectural design decisions support architecture evolution?

The architecture derivation process is basically an evolutionary process. Since architecture is regarded as a set of architectural design decisions, we primarily analyze the evolution of architectural design decisions to manage architecture evolution. The initial architectural design decisions results largely cover the functional requirements of the power plant monitoring system, from which we can obtain the architecture blueprint of the system. During the evolutionary change, the architectural decisions in the elements, the constraints, and the intent view should be tracked and updated with the changing scenarios and requirements. Here, we take the constraint view evolution as an example. For the constraint view, non-functional requirements influence the properties of the elements, and they may be changed after the components, the connectors, and the structure diagram of the system are derived. Specifically, as the architecting process proceeds, some quality attributes, e.g., reliability requirements, are more crucial for the whole system, and adding these quality requirements will make the system more realistic. For instance, we have basic requirement constraints between the FaultDetection Engine and the Alarm Manager in the initial architecture, and some new reliability requirements are added to the system afterward. One requirement may be “once a fault is detected by the FaultDetection Engine, the alarm should be raised within 5 seconds”. When this new limitation is included in the requirement specifications, we need to find out how it affects the current design decisions results. Based on the TVM, we find that the element view does not change, since there is no change on the syntax of the end-user scenarios. However, the constraint view is to be updated, because the “Check” factor of the property for the FaultDetectionAlarm connector should comply with the new requirement specification, i.e., we need to add “TimeConstraint=5s” to the “Check” factor. Most of the time, the intent view evolves together if the element view or the constraint view changes. Hence we also need to document the reason or the justification in the intent view, in order to specify why the time constraint should be within 5 seconds for the FaultDectection Alarm connector.

Generally, the architecture evolution process is based on the initial architectural design decisions results. When new requirements or new decisions via end-user scenarios arrive, we apply the SceMethod to the changing information to evolve the initial decisions. The SceMethod ensures that the architecture evolution results are consistent with the changing requirement specifications, and keeps architectural knowledge complete in the changing environment.

**E. Discussion**

1) **Practicality:** The TVM and the SceMethod, which are applied during the architecting and designing process, enable us to capture architectural design decisions and manage their evolution. As the software life cycle proceeds, the architectural design decisions results are widely employed throughout the entire software development process. Specifically, the documentation on architectural design decisions intuitively reflects development artifacts, such as the decisions in the element view, which trigger the implementation of the
By applying the TVM and the SceMethod, the architectural design decisions are employed in most of the software development phases, and finally architectural knowledge is well incorporated in various levels of the software development process.

2) Scalability: In the case study, we applied the TVM and the SceMethod to the power plant monitoring system and it worked well. As the system become more complex, for instance, more requirements need to be considered, our method can be applied incrementally. Each time we obtain new requirements, we describe them as scenarios by MSCs, and then follow the process of the SceMethod to derive the newly architectural design decisions. Our method right now is not quite applicable to distributed system, because the decision-collection mechanism in the SceMethod does not support for distributed environment. We try to improve this by providing tool support as integrating the SceMethod into configuration management tools, in order to better support the application and management of architectural decisions for complex systems.

3) Limitations: One limitation of the TVM and the SceMethod is lack of automatic traceability from architectural design decisions to requirement specifications. The automatic traceability between requirement and architectural knowledge will be more efficient when considering large-scale software systems, which have larger architectural design decisions set and more difficult to trace by hand. Therefore, tool support of the TVM and the SceMethod is also necessary to manage the traceability. Moreover, it may be useful to include a status for each decision to support the traceability. Another limitation is that current architectural design decisions results do not show the relations among each decision, and thus cannot provide in-depth architectural knowledge information. We aim to overcome this limitation by creating a network of the design decisions, through which we are capable of looking into further relationships of each decision, such as the cause and effect influence among them.

V. RELATED WORK

The key concepts of the traditional view on software architecture are components and connectors [1, 19]. Nowadays, software architecture has been seen as a set of architectural design decisions [2, 20, 21]. The architectural decisions in the software architecting process are increasingly focused by researchers and practitioners [22, 23], and architectural design decisions are also considered to be a part of architectural knowledge [3]. In [24], a systematic review for architectural knowledge is presented, and different definitions on architectural knowledge and how they are relevant to each other are discussed as well.

Guidelines for documenting software architecture has been provided in [25, 26], however, those documentation approaches do not explicitly capture architectural design decisions in the architecting process. Recently, many models and tools have been proposed for capturing, managing, and sharing architectural design decisions.

Tyree’s template [4] provides a simple document describing key architectural decisions, which establishes a concrete direction for design and implementation, and also clarifies the rationale for different stakeholders. In [3], an ontology of architectural design decisions and their relationships have been described. This ontology then can be used to construct architectural knowledge of a software system. ADDSS [5] is a web-based tool for documenting architectural design decisions. It establishes the backward and forward traceability between requirements, decisions, and architectures. Archium [6] is a Java tool, including a compiler and a run-time environment, for supporting architectural design decisions capturing, tracing, and managing. It also provides visualization for design decisions by using a dependency graph, which is easy for stakeholder to evaluate and track the decisions. Other models and tools such as AREL [27] and PAKME [28] are also proposed for managing architectural knowledge.

A detailed comparison of these existing models and tools has been done in [7]. Since each model has its own strong and weak points, it is still difficult for researchers and practitioners to choose which one is more suitable for their architecting process, and the existing models are hard to support architecture evolution very well [29]. Perry and Grisham have focused on architecture and design intent in [30], and our work in this paper tries to further generalize the concept of the intent and architectural decisions in software architecture and its evolution. Our TVM intends to provide a general architecture framework to clarify the notion of architectural design decisions, and the triple views perfectly cover the key features in software architecture. In addition, the SceMethod based on the TVM gives a simple and consistent way to manage the documentation and the evolution of architectural design decisions, which is effective in operating and maintaining the architecting process in a changing software development context.

VI. CONCLUSIONS AND FUTURE WORK

A recent strand of software architecture research is that software architecture is considered as a set of architectural design decisions. Architectural design decisions are also defined as a part of architectural knowledge, and are necessary to be documented and managed in order to
control fundamental problems in the software life cycle. In this paper, we discuss the documentation and evolution of architectural design decisions. We propose the Triple View Model (TVM) as a general architecture framework, which includes an element view, a constraint view, and an intent view to indicate “what”−“how”−“why” features for architectural design decisions. Based on the TVM, we present a scenario-based method (SceMethod) for architectural design decisions documentation and evolution. The case study on an industrial-strength project validates the applicability and effectiveness of the TVM and the SceMethod.

In our future work, we plan to provide tool support for the TVM and the SceMethod, and evaluate them in multiple large-scale software projects and complex systems.
